Multifingered robots play an important role in manipulation applications. They can grasp various shaped objects to perform point-to-point movement. It is important to plan the motion path of the object and appropriately control the grasping forces for multifingered robot manipulation. In this paper, we perform the optimal grasping control to find both optimal motion path of the object and minimum grasping forces in the manipulation. The rigid body dynamics of the object and the grasping forces subjected to the second-order cone (SOC) constraints are considered in optimal control problem. The minimum principle is applied to obtain the system equalities and the SOC complementarity problems. The SOC complementarity problems are further recast as the equations with the Fischer-Burmeister (FB) function. Since the FB function is semismooth, the semismooth Newton method with the generalized Jacobian of FB function is used to solve the nonlinear equations. The 2D and 3D simulations of grasping manipulation are performed to demonstrate the effectiveness of the proposed approach.

1. Introduction

Multifingered robots have attracted much attention in robotics manipulation applications. They can grasp various shaped objects and dexterously perform point-to-point manipulations. Many researches [1–6] have been proposed for grasping and manipulating objects with multifingered robots. Miller and Allen [2] proposed a user interface with grasp quality evaluation for the robot hand design. Yokohoji et al. [6] proposed a measure of dynamic manipulability of multifingered grasping for the systems consisting of a multifingered hand and a grasped object. Xu and Li [5] proposed a modeling method for the manipulation involving finger gaits. Kawamura et al. [1] used soft finger tips for stable grasping. Takahashi et al. [4] proposed robust force and position control with the information of tactile sensor. It is important to appropriately control the grasping forces for multifingered robot manipulation.

Since the grasping manipulation utilizes the contact and friction forces to hold and move an object, the grasping forces should satisfy the point-contact friction constraint and be equal to the dynamic wrench of the grasped object. It is required to find the minimum forces for moving the grasped object in the manipulation. Boyd and Wegbreit [7] used the semidefinite programming and second-order cone programming to efficiently find the grasping forces. Helmke et al. [8] proposed quadratically convergent algorithms for optimal dexterous grasping. Han et al. [9] used the convex optimization involving linear matrix inequalities for grasping forces computation. Liu et al. [10] presented a unified geometric framework for efficient grasping force optimization. Zheng et al. [11] developed an algorithm to determine the minimum required friction coefficient and the corresponding reliable minimum contact forces in practice. Ko et al. [12] proposed a neural network to calculate the optimal grasping forces. Because the external wrench of the object varies with
the manipulation path and orientation of the object, it is important to plan a manipulation trajectory \[13\] for achieving the minimum grasping forces.

In this paper, we perform the optimal grasping control to find both optimal manipulation path of the object and minimum grasping forces. The rigid body dynamics of the object and the grasping forces subjected to the second-order cone (SOC) constraints are considered in the grasping control problem. The minimum principle \[14\] is applied to obtain the system equalities and the SOC complementarity problems. The SOC complementarity problems can be recast as the equations with the Fischer-Burmeister (FB) function. The semismooth Newton method with the generalized Jacobian of FB function is then used to solve the equations. Finally, simulations of optimal grasping manipulation are performed to demonstrate the effectiveness of the proposed approach.

The remainder of this paper is organized as follows: Section 2 describes the optimal grasping control problem. In Section 3, the semismooth Newton method with the generalized Jacobian of Fischer-Burmeister function is addressed. Section 4 presents the simulation results of 2D and 3D grasping manipulations. Finally, concluding remarks are given in Section 5.

2. Optimal Grasping Control

Figure 1 shows the multifingered robot grasping manipulation. The multifingered robot grasps and moves the object from the initial position to the final position. The dynamic equation of the object can be expressed with Newton-Euler equations \[15,16\] as

\[
\dot{y} = V, \\
\dot{V} = \frac{1}{m} RG_1 u + \begin{bmatrix} 0 & 0 & -g \end{bmatrix}^T, \\
\dot{q} = Q \omega, \\
\omega = I^{-1} (RG_2 u - \omega \times (I \omega)),
\]

(1)

where \(y\) is the position, \(V\) is the velocity, \(q = [q_1 \ q_2 \ q_3]^T\) is the quaternion, \(\omega\) is the angular velocity, \(m\) is the object mass, \(I\) is the matrix of moment of inertia, \(g\) is the gravity constant, \(u\) means the grasping forces which is represented by a matrix, \([G_1 \ G_2]\) is the contact matrix, \(R\) is the rotation matrix of the object, and \(Q\) can be expressed as

\[
Q = \frac{1}{2} \begin{bmatrix} q_0 & q_3 & -q_2 \\ -q_3 & q_0 & q_1 \\ q_2 & -q_1 & q_0 \end{bmatrix} \quad \text{with} \quad q_0 = \sqrt{q_1^2 + q_2^2 + q_3^2}. 
\]

(2)

Moreover, the grasping forces are subject to the contact friction constraint, expressed as

\[
\| (u_{i2}, u_{i3}) \| \leq \mu u_{i1},
\]

(3)

where \(u_{i1}\) is the normal force of the \(i\)th finger, \(u_{i2}\) and \(u_{i3}\) are the friction forces of the \(i\)th finger, \(\| \cdot \|\) is the 2-norm, and \(\mu\) is the friction coefficient.

To find the path that can be achieved with the minimum grasping forces, the optimal control problem can be recast as

\[
\min \int_0^T L \, dt, \\
\text{s.t.} \quad \dot{x} = f(x, u), \\
x(0) = x_0, \\
x(T) = x_T, \\
Du \in \mathcal{K}^d \times \mathcal{K}^d \times \cdots \times \mathcal{K}^d,
\]

(4)

where

\[
L = \frac{u^T u}{2}, \quad x = \begin{bmatrix} y \\ V \\ q \\ \omega \end{bmatrix}.
\]

(5)

In addition, \(f\) represents the right hand side of system (1), \(T\) is the control duration, \(x_0\) and \(x_T\) are the initial and final states, respectively, \(D\) is the diagonal matrix with the friction coefficient, and \(\mathcal{K}\) denotes the second-order cone which is given by

\[
\mathcal{K}^d := \left\{ \begin{bmatrix} z_1 \\ z_2 \\ \vdots \\ z_d \end{bmatrix} \in \mathbb{R} \times \mathbb{R}^{d-1} \mid \|z_2\| \leq z_1 \right\}.
\]

(6)

The optimal control problem (4) can be solved by using the Pontryagin’s minimum principle, see \[14, 17, 18\]. In optimization language, it is to write out the KKT conditions for problem (4) which consist of two parts. The first part involves a few equalities about Lagrange multipliers, while the other part is related to complementarity conditions. More specifically, with the Hamiltonian function, the first part can be reformulated as follows:

\[
\dot{x} - H_\lambda = \dot{x} - f(x, u) = 0, \\
\lambda + H_\mu = \dot{\lambda} + \lambda^T f_x = 0,
\]

(7)

\[
H_u = L_u + \lambda^T f_u + \eta^T D = 0, \\
\phi(x(0), x(T)) = 0, \\
\lambda(0) + \phi_{x(0)} \sigma = 0, \\
\lambda(T) + \phi_{x(T)}^T \sigma = 0,
\]

where \(\phi(x(0), x(T))\) is the constraint function, and \(\phi_{x(0)} \sigma\) and \(\phi_{x(T)}^T \sigma\) are the Lagrange multipliers associated with the initial and final state constraints, respectively.
where $\lambda$, $\eta$, and $\sigma$ are the Lagrange multipliers, and $\phi(x(0), x(T)) = \begin{bmatrix} x(t_0) - x_l \\ x(T) - x_u \end{bmatrix}$. The second part forms a second-order cone complementarity problem (SOCCP) as follows:

$$-\eta \in K, \quad Du \in K, \quad \eta^T Du = 0,$$

where $K = K_d \times K_d \times \cdots \times K_d$. From [19, 20], we see that the previous SOCCP (8) can be further recast as a system of equations:

$$\phi_{FB}(Du, -\eta) = 0$$

by employing the so-called complementarity function $\phi_{FB}$ which is a vector-valued function defined as

$$\phi_{FB}(a, b) := \left( a^2 + b^2 \right)^{1/2} - (a + b)$$

for $a = [a_1 \ldots a_d] \in \mathbb{R} \times \mathbb{R}^{d-1}$, $b = [b_1 \ldots b_d] \in \mathbb{R} \times \mathbb{R}^{d-1}$. We point out that the square term and square-root term in (10) are calculated via Jordan product

$$a \circ b = \begin{bmatrix} a^T b \\ a_1 b_2 + b_1 a_2 \end{bmatrix}. \quad \text{(11)}$$

In particular, the expressions for $a^2$ and $a^{1/2}$ are given by

$$a^2 = \begin{bmatrix} \|a\|^2 \\ 2a_1 a_2 \end{bmatrix}, \quad \text{(12)}$$

$$a^{1/2} = \begin{bmatrix} s \\ \frac{a_2}{s} \end{bmatrix} \quad \text{with} \quad s = \sqrt{\frac{1}{2} \left( a_1 + \sqrt{a_1^2 - \|a\|^2} \right)}.$$. \quad \text{(13)}$$

respectively.

In summary, the optimal grasping forces can be obtained by solving (7) and (9). Then, the semismooth Newton method is used to solve these equations, which will be described in next section.

\section{3. Semismooth Newton Method with Generalized Jacobian of FB Function}

In order to apply the semismooth Newton method [21, 22] to (7) and (9), we need the following three linear equations:

$$\begin{bmatrix} \Delta \dot{x} \\ \Delta \dot{\lambda} \end{bmatrix} - \begin{bmatrix} f_{x}^{(k)} \\ -H_{xx}^{(k)} \end{bmatrix} \begin{bmatrix} \Delta x \\ \Delta \lambda \end{bmatrix} - \begin{bmatrix} f_{x}^{(k)} \\ -H_{xx}^{(k)} \end{bmatrix} \begin{bmatrix} \Delta u \\ \Delta \eta \end{bmatrix} = - \begin{bmatrix} \phi_{x}^{(k)}(x(0)) \\ \phi_{\lambda}^{(k)}(x(0)) \end{bmatrix},$$

$$\begin{bmatrix} \phi_{x}^{(k)}(x(0)) \\ \phi_{\lambda}^{(k)}(x(0)) \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \end{bmatrix} \begin{bmatrix} \phi_{x}^{(k)}(x(T)) \\ \phi_{\lambda}^{(k)}(x(T)) \end{bmatrix} = \begin{bmatrix} \phi_{x}^{(k)}(T) \\ \phi_{\lambda}^{(k)}(T) \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \end{bmatrix} \begin{bmatrix} \phi_{x}^{(k)}(T) \\ \phi_{\lambda}^{(k)}(T) \end{bmatrix},$$

\text{(14)}

In order to apply the semismooth Newton method [21, 22] to

\begin{align*}
\begin{bmatrix}
\Delta \dot{x} \\
\Delta \dot{\lambda}
\end{bmatrix} &= - \begin{bmatrix}
f_{x}^{(k)} \\
-H_{xx}^{(k)}
\end{bmatrix} \begin{bmatrix}
\Delta x \\
\Delta \lambda
\end{bmatrix} - \begin{bmatrix}
f_{x}^{(k)} \\
-H_{xx}^{(k)}
\end{bmatrix} \begin{bmatrix}
\Delta u \\
\Delta \eta
\end{bmatrix} \\
&= - \begin{bmatrix}
\phi_{x}^{(k)}(x(0)) \\
\phi_{\lambda}^{(k)}(x(0))
\end{bmatrix} \\
&\quad + \begin{bmatrix}
0 \\
0
\end{bmatrix} \begin{bmatrix}
\phi_{x}^{(k)}(x(T)) \\
\phi_{\lambda}^{(k)}(x(T))
\end{bmatrix} \\
&= \begin{bmatrix}
\lambda^{(k)}(0) \\
\phi_{x}^{(k)}(x(0)) \sigma^{(k)}(0)
\end{bmatrix} + \begin{bmatrix}
0 \\
0
\end{bmatrix} \begin{bmatrix}
\lambda^{(k)}(T) \\
\phi_{x}^{(k)}(x(T)) \sigma^{(k)}(T)
\end{bmatrix},
\end{align*}

\text{(15)}

where $\lambda^{(k)}$ and $\sigma^{(k)}$ are the Lagrange multipliers, and $\phi(x(0), x(T)) = [x(t_0) - x_l \\
x(T) - x_u]$. The second part forms a second-order cone complementarity problem (SOCCP) as follows:

$$-\eta \in K, \quad Du \in K, \quad \eta^T Du = 0,$$

where $K = K_d \times K_d \times \cdots \times K_d$. From [19, 20], we see that the previous SOCCP (8) can be further recast as a system of equations:

$$\phi_{FB}(Du, -\eta) = 0$$

by employing the so-called complementarity function $\phi_{FB}$ which is a vector-valued function defined as

$$\phi_{FB}(a, b) := \left( a^2 + b^2 \right)^{1/2} - (a + b)$$

for $a = [a_1 \ldots a_d] \in \mathbb{R} \times \mathbb{R}^{d-1}$, $b = [b_1 \ldots b_d] \in \mathbb{R} \times \mathbb{R}^{d-1}$. We point out that the square term and square-root term in (10) are calculated via Jordan product

$$a \circ b = \begin{bmatrix} a^T b \\
a_1 b_2 + b_1 a_2 \end{bmatrix}. \quad \text{(11)}$$

In particular, the expressions for $a^2$ and $a^{1/2}$ are given by

$$a^2 = \begin{bmatrix} \|a\|^2 \\
2a_1 a_2 \end{bmatrix}, \quad \text{(12)}$$

$$a^{1/2} = \begin{bmatrix} s \\
\frac{a_2}{s} \end{bmatrix} \quad \text{with} \quad s = \sqrt{\frac{1}{2} \left( a_1 + \sqrt{a_1^2 - \|a\|^2} \right)}.$$. \quad \text{(13)}$$

respectively.

In summary, the optimal grasping forces can be obtained by solving (7) and (9). Then, the semismooth Newton method is used to solve these equations, which will be described in next section.
Forces (N)

Figure 5: The manipulation path of 90 degrees rotation with $T = 1$ s and $\mu = 0.1$.

Figure 6: The manipulation path of 180 degrees rotation with $T = 1$ s and $\mu = 0.3$.

Figure 7: The manipulation path of 180 degrees rotation with $T = 2$ s and $\mu = 0.3$.

Most information in linear equations (14)–(16) is known except the generalized Jacobian $V_a, V_b$ in (16). What do they represent? We provide a brief introduction here. First, we recall the concept of the $B$-subdifferential. Given a mapping $\Psi: \mathbb{R}^n \to \mathbb{R}^m$, if $\Psi$ is locally Lipschitz continuous, then the set

$$\partial_B H (z) := \{ V \in \mathbb{R}^{m \times n} | \exists \{ z^k \} \subseteq D_{\Psi} : z^k \to z, \Psi' (z^k) \to V \}$$

(17)
is nonempty and is called the $B$-subdifferential of $\Psi$ at $z$, where $D_\Psi \subseteq \mathbb{R}^n$ denotes the set of points at which $\Psi$ is differentiable. The convex hull

$$\partial \Psi (z) := \operatorname{conv} \partial_B \Psi (z)$$

is the generalized Jacobian of Clarke [23]. From this definition, we see that the generalized Jacobian of $\phi_{FB}$ can be obtained by computing $\partial_B \phi_{FB}$. From [24, Proposition 3.1], the $B$-subdifferential of $\phi_{FB}$ in (16) is exactly expressed as

$$\partial_B \phi_{FB} (\mathbf{a}, \mathbf{b}) = \begin{bmatrix} \mathbf{V}_a^T \\ \mathbf{V}_b^T \end{bmatrix}.$$  \hfill (19)

Moreover, by denoting $\mathbf{c} := (\mathbf{a}^2 + \mathbf{b}^2)^{1/2}$, we have

(a) If $\mathbf{a}^2 + \mathbf{b}^2 \in \text{int}(\mathcal{K})$, then $V_a = L_c^{-1}L_a$ and $V_b = L_c^{-1}L_b$.

(b) If $\mathbf{a}^2 + \mathbf{b}^2 \in \partial \mathcal{K}$ and $(\mathbf{a}, \mathbf{b}) \neq (\mathbf{0}, \mathbf{0})$, then

$$V_a \in \left\{ \frac{1}{2\sqrt{2w_1}} \left( \frac{1}{w_2} \begin{bmatrix} \bar{w}_2^T \\ 4I - 3\bar{w}_2\bar{w}_2^T \end{bmatrix} L_a + \frac{1}{2} \begin{bmatrix} \frac{1}{w_2} \alpha^T \end{bmatrix} \right) \right\},$$

$$V_b \in \left\{ \frac{1}{2\sqrt{2w_1}} \left( \frac{1}{w_2} \begin{bmatrix} \bar{w}_2^T \\ 4I - 3\bar{w}_2\bar{w}_2^T \end{bmatrix} L_b + \frac{1}{2} \begin{bmatrix} \frac{1}{w_2} \beta^T \end{bmatrix} \right) \right\}.$$  \hfill (20)
for some $\alpha = [\alpha_1, \alpha_2] \in \mathbb{R} \times \mathbb{R}^{d-1}$ and $\beta = [\beta_1, \beta_2] \in \mathbb{R} \times \mathbb{R}^{d-1}$ satisfying $|\alpha_1| \leq \|\alpha_2\| \leq 1$ and $|\beta_1| \leq \|\beta_2\| \leq 1$, where $\bar{w}_2 = w_2/\|w_2\|$. 

(c) If $(a, b) = (0, 0)$, then $V_a \in \{L_{\bar{a}}\}$, $V_b \in \{L_{\bar{b}}\}$ for some $\bar{a}, \bar{b}$ with $\|\bar{a}\|^2 + \|\bar{b}\|^2 = 1$, or

$$V_a \in \left\{ \frac{1}{2} \left( \frac{1}{\bar{w}_2} \right) \gamma^T + \frac{1}{2} \left( \frac{-1}{\bar{w}_2} \right) \alpha^T + 2 \left( (I - \bar{w}_2 \bar{w}_2^T) \delta_2 (I - \bar{w}_2 \bar{w}_2^T) \delta_1 \right) \right\},$$

$$V_b \in \left\{ \frac{1}{2} \left( \frac{1}{\bar{w}_2} \right) \gamma^T + \frac{1}{2} \left( \frac{-1}{\bar{w}_2} \right) \beta^T + 2 \left( (I - \bar{w}_2 \bar{w}_2^T) \gamma_2 (I - \bar{w}_2 \bar{w}_2^T) \gamma_1 \right) \right\}.$$

Figure 11: The trajectories of the grasping forces in five-fingered robot simulation.

Figure 12: The 3D manipulation path of the four-fingered robot.

Figure 13: The 3D manipulation path of the six-fingered robot.
for some $\alpha = [\alpha_1^T], \beta = [\beta_1^T], \xi = [\xi_1^T], \tau = [\tau_1^T] \in \mathbb{R} \times \mathbb{R}^{l \times 1}$ such that

$$
|\alpha_1| \leq \|\alpha_2\| \leq 1, \quad |\beta_1| \leq \|\beta_2\| \leq 1, \\
|\xi_1| \leq \|\xi_2\| \leq 1, \quad |\tau_1| \leq \|\tau_2\| \leq 1,
$$

(22)

$\mathbf{w}_2 \in \mathbb{R}^{l \times 1}$ satisfying $\|\mathbf{w}_2\| = 1$, and $\delta = [\delta_1^T], \gamma = [\gamma_1^T] \in \mathbb{R} \times \mathbb{R}^{l \times 1}$ satisfying $\|\delta\|^2 + \|\gamma\|^2 \leq 1/2$.

Note that the calculations of $L_a$ and $L_a^{-1}$ are given by

$$
L_a = \begin{bmatrix} a_1 & a_2^T \\ a_2 & a_1 I \end{bmatrix},
$$

$$
L_a^{-1} = \frac{1}{a_1^2 - \|a_2\|^2} \begin{bmatrix} a_1 & -a_2^T \\ -a_2 & \|a_2\|^2/a_1 I - a_1 a_2 a_2^T \end{bmatrix}. 
$$

(23)

For more details, please refer to [24]. Now, we write down the iterative scheme of semismooth Newton method for solving the optimal grasping control problem.

**Algorithm**

**Step 1.** Choose $x^0, u^0, \lambda^0, \eta^0, \sigma^0$ and set $k = 0$.

**Step 2.** If convergence criterion is satisfied, stop.

**Step 3.** Compute the direction $\Delta x^k, \Delta u^k, \Delta \lambda^k, \Delta \eta^k, \Delta \sigma^k$ from the linear equations (14)–(16).

**Step 4.** Set

$$
\begin{bmatrix}
\lambda^{k+1} \\
u^{k+1} \\
\lambda^{k+1} \\
\eta^{k+1} \\
\sigma^{k+1}
\end{bmatrix} =
\begin{bmatrix}
x^k \\
u^k \\
\lambda^k \\
\eta^k \\
\sigma^k
\end{bmatrix} +
\begin{bmatrix}
\Delta x^k \\
\Delta u^k \\
\Delta \lambda^k \\
\Delta \eta^k \\
\Delta \sigma^k
\end{bmatrix}, \quad k = k + 1
$$

(24)

and go to Step 2.

A few words about the implementations. From (14) and (16), the parameters $[\Delta \lambda/\Delta \sigma]$ can be eliminated and the differential equations regarding $[\Delta \lambda/k]$ are obtained. With the boundary conditions (15), the solutions of $[\Delta \lambda/k]$ can be achieved. Finally, the solutions of $[\Delta \lambda/\Delta \sigma]$ can be obtained by (16). Once all linear equations are solved by the above procedures, the iterative scheme for the calculation of optimal grasping force is kept going.

**4. Simulations**

To evaluate the performance of the proposed approach, we do simulations for 2D and 3D multifingered robots for grasping manipulations. The 2D grasping simulations are performed with a plane three-fingered robot. The parameter values of the object are $m = 1$ kg, $I = 0.01$ kgm$^2$, $\mu = 0.6$, and the grasping matrices are

$$
G_1 = \begin{bmatrix} 0 & 1 & 0 & -1 & 0 & -1 \\ -1 & 0 & 1 & 0 & 1 & 0 \end{bmatrix},
$$

(25)

$$
G_2 = [0 -0.03 -0.03 0.03 0.03 0.03].
$$

The first 2D simulation is the manipulation of 90 degrees rotation of the object. The start and end points $(x, y, \theta)$ are set to be $(0 \text{ m}, 0 \text{ m}, 0 \text{ rad})$ and $(1 \text{ m}, 1 \text{ m}, -(\pi/2) \text{ rad})$, respectively. Figure 2 shows the manipulation path of 90 degrees rotation with the time $T = 1 \text{ s}$ and the friction coefficient $\mu = 0.3$. The simulation result indicates that the proposed scheme grasps the object to the end point smoothly and accurately. Figure 3 depicts the trajectories of the variables $x, y, \theta, v_x, v_y$, and $\omega$. We observe that the rotation angle $\theta$ varies around 0 which results in a small grasping force. Moreover, the translation speeds are kept within 1.8 m/s and the turning speed within 5.5 rad/s. The trajectories of the grasping forces are shown in Figure 4. The simulation results show that the normal forces are all nonnegative and the tangent forces satisfy the friction constraint. To evaluate the effect of the friction, simulation with a different value of friction coefficient is also conducted for 90 degrees rotation simulation. Figure 5 shows the manipulation path with the friction coefficient $\mu = 0.1$. We observe that the manipulation path length becomes longer as the friction coefficient decreases. Meanwhile, the value of the objective function $J$ is computed to be 3.07 when $\mu$ was 0.3 and it becomes 3.39 when $\mu$ reduces to 0.1, leading to the increase in grasping force.

The second 2D simulation is the manipulation of 180 degrees rotation of the object. The start and end points $(x, y, \theta)$ are set to be $(0 \text{ m}, 0 \text{ m}, -(\pi/2) \text{ rad})$ and $(1 \text{ m}, 1 \text{ m}, (\pi/2) \text{ rad})$, respectively. The friction coefficient is set as $\mu = 0.3$. Figures 6-7 depict the manipulation paths of 180 degrees rotation with the time $T = 1 \text{ s}$ and $T = 2 \text{ s}$, respectively. We observe that the object moves down initially and reaches to the end point accurately. Moreover, the mean of rotation angle decreases as $T$ increases.

The 3D grasping simulation is performed with a five-fingered robot which has not been implemented in the literature. The object is considered as a block and its parameter values were set as

$$
m = 1 \text{ kg}, \quad I_{11} = 8.33e - 3 \text{ kgm}^2,
$$

$$
I_{22} = 4.17e - 3 \text{ kgm}^2, \quad I_{33} = 1.08e - 2 \text{ kgm}^2.
$$

(26)

The two fingers of the robot grasp the top of the object, while the other three grasp the bottom of the object. The matrices $G_1$ and $G_2$ are
In this paper, we have proposed an effective method for multifingered robot path planning and grasping forces computation. The optimal grasping control problem was formulated with the rigid body dynamics of the object and the second-order cone constraints of grasping forces. The SOC complementarity problem was recast as the equations with the Fischer-Burmeister (FB) function, and the semismooth Newton method with the generalized Jacobian of FB function was used to solve the system equations. The simulation results show that the optimal grasping forces can accurately move the object to a goal, demonstrating the effectiveness of the proposed method.

5. Conclusion

In this paper, we have proposed an effective method for multifingered robot path planning and grasping forces computation. The optimal grasping control problem was formulated with the rigid body dynamics of the object and the second-order cone constraints of grasping forces. The SOC complementarity problem was recast as the equations with the Fischer-Burmeister (FB) function, and the semismooth Newton method with the generalized Jacobian of FB function was used to solve the system equations. The simulation results show that the optimal grasping forces can accurately move the object to a goal, demonstrating the effectiveness of the proposed method.
