

雙語教學主題(國中九年級上學期教材): 三角形的重心

Topic: The centroid of a triangle

The teaching materials for introducing circles in our textbooks have been changed quite a bit due to the **108 syllabus**. Therefore, the content here is based on the official textbooks-NANI, KANG HSUAN and HANLIN.

由於 108 新綱教材大改，所以這個單元參考 108 新課綱及南一、康軒及翰林版國中數學課本第五冊

Vocabulary

centroid, median, vertex, vertices, congruent, equidistant,

Before we start introducing this new lesson, we want to introduce a new word median.

As shown in the figure on the right, in $\triangle ABC$, point M is the midpoint of segment AB. Then \overline{AM} is a median.

We can easily prove that

The area of $\triangle ABM$ = the area of $\triangle ACM$ = $\frac{1}{2}$ the area of $\triangle ABC$

For teachers' reference (students can try to prove it themselves)

Pf:

In $\triangle ABC$, $\overline{AH} \perp \overline{BC}$ and \overline{AH} intersects \overline{BC} at point H, as shown in figure 1.

$$\text{The area of } \triangle ABC = \frac{1}{2} \overline{BC} \times \overline{AH}$$

$$\text{The area of } \triangle ABM = \frac{1}{2} \overline{BM} \times \overline{AH}$$

$$\text{The area of } \triangle ACM = \frac{1}{2} \overline{CM} \times \overline{AH}$$

Figure 1

Since point M is a midpoint of segment BC

$$\overline{BM} = \overline{CM} = \frac{1}{2} \overline{BC}$$

We get

$$\text{The area of } \triangle ABM = \frac{1}{2} \overline{BM} \times \overline{AH} = \frac{1}{4} \overline{BC} \times \overline{AH} = \frac{1}{4} \text{the area of } \triangle ABC$$

$$\text{The area of } \triangle ACM = \frac{1}{2} \overline{CM} \times \overline{AH} = \frac{1}{4} \overline{BC} \times \overline{AH} = \frac{1}{4} \text{the area of } \triangle ABC$$

That is:

$$\text{The area of } \triangle ABM = \text{the area of } \triangle ACM = \frac{1}{4} \text{the area of } \triangle ABC$$

So the statement is true. #

Now let's learn what the centroid of a triangle is.

Centroid:

Figure 1 shows that \overline{BE} and \overline{CD} are two medians in $\triangle ABC$, and they intersect each other at point G.

Figure 1

As we mention in the beginning, \overline{BE} is a median of $\triangle ABC$, then the area of $\triangle ABE$ = the area of $\triangle CBE$, this means the center of gravity (center of mass) of this triangle must lie on \overline{BE} . \overline{CD} is also a median of $\triangle ABC$. Therefore, we know that the intersection point G is the center of gravity of $\triangle ABC$.

We have learned that in a triangle, three perpendicular bisectors of three sides will intersect at one point, and three angle bisectors of three interior angles will intersect at one point. If we construct the third median in $\triangle ABC$, will these three medians also intersect at one point?

Connect \overline{DE} as shown in figure 2.

By midsegment theorem, $\overline{DE} \parallel \overline{BC}$ and $\overline{DE} = \frac{1}{2} \overline{BC}$

Figure 2

In $\triangle DEG$ and $\triangle CBG$,

$\angle DEG = \angle CBG$ ($\overline{DE} \parallel \overline{BC}$, the alternate interior angles are equal)

$\angle DGE = \angle CGB$ (the vertical angles are equal)

(of course you can use the same reason as the first one with $\angle EDG = \angle BCG$)

We get $\triangle DEG \sim \triangle CBG$ (AA)

Then $\overline{DG} : \overline{CG} = \overline{EG} : \overline{BG} = \overline{DE} : \overline{BC} = 1 : 2$ ($\overline{DE} = \frac{1}{2} \overline{BC}$)

Figure 3

In figure 3, connect \overline{AF} where point F

is the midpoint of \overline{BC} . And assume \overline{AF} intersects \overline{BE} at a point G' .

Similarly, $\overline{EG'} : \overline{BG'} = 1 : 2$, but $\overline{EG} : \overline{BG} = 1 : 2$

Point G and point G' are both on segment BE

Therefore, Point G and point G' must be the same point

That means the third median \overline{AF} also passes through the centroid

We get the conclusion that

Three medians of a triangle will intersect at one point, centroid.

We can see in figure 4 that no matter what kind of triangle it is, the centroid of the triangle always stays inside the triangle.

Figure 4

From the discussion above, we get a very important result that

$$\overline{AG}=2\overline{FG}, \overline{BG}=2\overline{EG}, \text{ and } \overline{CG}=2\overline{DG}:$$

Now let's talk about some important properties concerning centroids of triangles

In figure 1 on the right side, point G is the centroid of $\triangle ABC$, connect \overline{AG} , \overline{BG} , and \overline{CG} .

Then the area of $\triangle AGB =$ the area of $\triangle BGC =$ the area of $\triangle CGA$ Figure 1

$$= \frac{1}{3} \text{ (the area of } \triangle ABC \text{)}$$

Pf: in figure 2, construct \overline{AG} , and \overline{AG} intersects

\overline{BC} at point D. And construct $\overline{BB'} \perp \overline{AG}$

and intersects \overline{AG} at point B',

construct $\overline{CC'} \perp \overline{AG}$ and intersects \overline{AG} at point C'.

In $\triangle BB'D$ and $\triangle CC'D$,

$$\angle BB'D = \angle CC'D = 90^\circ \quad (\overline{BB'} \perp \overline{AG}, \overline{CC'} \perp \overline{AG}) \quad \text{Figure 2}$$

$$\angle BDB' = \angle CDC' \quad (\text{vertical angles are equal})$$

$$\overline{BD} = \overline{CD} \quad (\text{point G is the centroid, so point D is the midpoint of segment BC.})$$

Then $\triangle BB'D \cong \triangle CC'D$ (AAS)

$$\overline{BB'} = \overline{CC'} \quad (\text{corresponding segments are congruent})$$

In $\triangle ABG$, the area of $\triangle ABG = \frac{1}{2} \cdot \overline{AG} \cdot \overline{BB'}$

and in $\triangle ACG$, the area of $\triangle ACG = \frac{1}{2} \cdot \overline{AG} \cdot \overline{CC'}$

the area of $\triangle ABG =$ the area of $\triangle ACG$ (same base and congruent height)

Similarly, we can get the conclusion that

$$\text{the area of } \triangle ABG = \text{the area of } \triangle ACG = \text{the area of } \triangle BCG$$

$$\therefore \text{the area of } \triangle ABC$$

$$= \text{the area of } \triangle ABG + \text{the area of } \triangle ACG + \text{the area of } \triangle BCG$$

We get the area of $\triangle ABG =$ the area of $\triangle ACG =$ the area of $\triangle BCG$

$$= \frac{1}{3} (\text{the area of } \triangle ABC) \#$$

You can have lots of methods to get the result above, please try your best to think and enjoy the process.

If we construct three medians of a triangle, we can get the result as follows:

In figure 3, \overline{AD} , \overline{BE} , and \overline{CF} are medians of $\triangle ABC$.

Let the area of $\triangle AFG=a$, $\triangle BFG=b$, $\triangle BDG=c$, $\triangle CDG=d$, $\triangle CEG=e$, and $\triangle AEG=f$, then $a=b=c=d=e=f$

Pf:

Figure 3

In figure 4, construct $\overline{GH} \perp \overline{BC}$ and intersects \overline{BC} at point H.

Then $c = \frac{1}{2} \overline{BD} \cdot \overline{GH} = \frac{1}{2} \overline{CD} \cdot \overline{GH} = d$ ($\overline{BD} = \overline{CD}$)

With the similar process, we get

$$a=b=c=d=e=f_{\#}$$

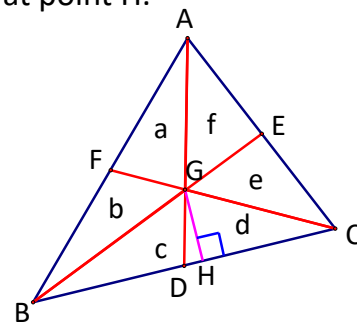

Figure 4

Let's do some examples here.

Ex 1:

Point G is the centroid of right triangle ABC. Point D is the midpoint of segment BC, $\overline{AC}=10$, $\overline{BC}=6$.

Please find out:

(1) the length of \overline{AG}

(2) the area of $\triangle ABG$

Sol:

$$(1) \overline{AG} = \frac{2}{3} \overline{AD} = \frac{2}{3} \sqrt{\overline{AB}^2 + \overline{BD}^2}$$

By Pythagorean theorem

$$\overline{AB}^2 = \overline{AC}^2 - \overline{BC}^2 = 10^2 - 6^2 = 64$$

$$\overline{BD} = \frac{1}{2} \overline{BC} = \frac{1}{2} \cdot 6 = 3$$

$$\overline{AG} = \frac{2}{3} \overline{AD} = \frac{2}{3} \sqrt{\overline{AB}^2 + \overline{BD}^2} = \frac{2}{3} \sqrt{64 + 9} = \frac{2}{3} \sqrt{73}$$

(2) the area of $\triangle ABG = \frac{1}{3}$ the area of $\triangle ABC$

$$= \frac{1}{3} \cdot \frac{1}{2} \cdot 8 \cdot 6$$

$$= 8_{\#}$$

Ex 2:

Two diagonals in rhombus ABCD \overline{AC} and \overline{BD} intersect each other at point O. Point E is the midpoint of segment CD.

$\overline{EF}=2$, $\overline{CF}=4$. Please find out:

- (1) the length of segment BF
- (2) the length of segment OF
- (3) the length of segment BO
- (4) the area of $\triangle CEF$
- (5) the area of rhombus ABCD

Sol:

The two diagonals of a rhombus are perpendicular and bisect each other.

Point O is the midpoint of \overline{BD} and point E is the midpoint of \overline{CD} .

(1) $\overline{BF}=2\overline{EF}=2\cdot 2=4$ (property of centroid)

(2) $\overline{OF}=\frac{1}{2}\overline{CF}=\frac{1}{2}\cdot 4=2$

(3) apply the Pythagorean theorem,

$$\overline{OB}^2 = \overline{BF}^2 - \overline{OF}^2 = 4^2 - 2^2 = 12$$

$$\overline{OB} = 2\sqrt{3}$$

(4) the area of $\triangle CEF =$ the area of $\triangle OBF$

$$= \frac{1}{2} \cdot \overline{OB} \cdot \overline{OF}$$

$$= \frac{1}{2} \cdot 2\sqrt{3} \cdot 2$$

$$= 2\sqrt{3}$$

(5) the area of rhombus ABCD = 12 · the area of $\triangle OBF$

$$= 12 \cdot 2\sqrt{3} = 24\sqrt{3}_{\#}$$

Let's wrap up the key information as follows:

TYPE FEATURES	CIRCUMCENTER	INCENTER	CENTROID
INTERSECTION POINT OF	PERPENDICULAR BISECTORS OF THREE SIDES	ANGLE BISECTORS OF THREE INTERIOR ANGLES	THREE MEDIANS
POSITION	ACUTE Δ INTERIOR OF Δ RIGHT Δ ON THE MIDPOINT OF HYPOTENUSE OBTUSE Δ EXTERIOR OF Δ	ALWAYS INTERIOR OF Δ	ALWAYS INTERIOR OF Δ
EQUIDISTANT TO	THREE VERTICES	THREE SIDES	X
CENTER OF	CIRCUMCIRCLE	INCIRCLE	X

There is so much to learn in this lesson. Please review it thoroughly. And do more practice is a must.

Watch and enjoy: Center of gravity
